ANTI-GUANYLYL CYCLASE β1, SOLUBLE (SN-15)
Developed in Rabbit, Affinity Isolated Antibody

**Product Description**

Anti-Soluble Guanylyl Cyclase β1 is developed in rabbit using a synthetic peptide corresponding to amino acid residues 605-619 of rat soluble Guanylyl cyclase β1 with N-terminal added lysine, conjugated to KLH with glutaraldehyde, as immunogen. The sequence differs in human, bovine and mouse by 3, 1 and 2 amino acids, respectively. The antibody is affinity-purified using the immunizing peptide immobilized on agarose.

Anti-Soluble Guanylyl Cyclase β1 (sGCβ1) specifically recognizes sGCβ1 by immunoblotting and immunoprecipitation (~70 kDa). Additional weak bands may be detected in some preparations of brain extracts by immunoblotting. Staining of the sGCβ1 band is specifically inhibited with the immunizing peptide. Also, the antibody may be used for the detection of sGCβ1 by immunohistochemistry. The epitope(s) recognized by the antibody is compatible with routine formalin-fixation and paraffin-embedding. The antibody reacts with sGCβ1 of human and rat origin. It is expected to react with bovine and mouse sGCβ1 due to the sequence homology, but this has not been tested.

Soluble guanylyl cyclase [sGC; GTP pyrophosphohydrase (cyclizing); (EC 4.6.1.2)] catalyses in a Mg2+ or Mn2+ dependent manner the conversion of guanosine-5’-triphosphate (GTP) to cyclic guanosine-3’,5’-monophosphate (cGMP) and pyrophosphate.1,2 sGC is an obligate hemoprotein enzyme consisting of α and β subunits of ~80 kDa and ~70 kDa respectively, both required for catalytic activity.3 At least two main different α and two β subunits have been identified in human tissues.4

The enzyme is a major physiological receptor for nitric oxide (NO), an important intra- and intercellular membrane-permeant signaling molecule. Gaseous NO binds to Fe2+ in the prosthetic heme group of sGC. NO binding is followed by disruption of the β1 subunit histidine 105 bond to iron and activation of the enzyme.1,2,5 The N-terminal domains of the subunits are essential for the stimulation of the enzyme by NO. A central portion of the sGC molecule mediates dimerization.

The C-terminus domain of both subunits, also conserved in plasma membrane-bound guanylyl cyclase and in adenylyl cyclases, forms the catalytic domain. cGMP regulates various effector proteins, such as protein kinases (e.g. PKG), phosphodiesterases and ion-channels.6 The NO-sGC-cGMP signaling pathway is important in regulating a great variety of physiological processes including smooth muscle relaxation, inflammation, platelet adhesion and aggregation, pulmonary physiology and neuronal function.1,2,6,7 sGC is constitutively expressed in a wide variety of animals including vertebrates, insects and molluscs. It is found in the cell cytoplasm of virtually all mammalian cells although the β2 subunit might also be associated with cell membranes. Non-uniform distribution of sGC isoforms α1 and β1 has been found in rat brain.8 Due to its ubiquitous nature, sGC may have considerable pathophysiological significance. It is an important target for NO-releasing and non-NO-releasing activator drugs in human cardiovascular therapy.4,9

**Reagent**

Anti-Soluble Guanylyl Cyclase β1 is supplied as an affinity isolated antibody in 10 mM phosphate buffered saline, pH 7.4, containing 1% bovine serum albumin and 15 mM sodium azide.

Protein concentration is approximately 1 mg/ml.

**Precautions and Disclaimer**

Due to the sodium azide content a material safety sheet (MSDS) for this product has been sent to the attention of the safety officer of your institution. Consult the MSDS for information regarding hazardous and safe handling practices.

**Storage/Stability**

For continuous use, store at 2 °C to 8 °C for up to one month. For extended storage, freeze in working aliquots. Repeated freezing and thawing is not recommended. Storage in "frost-free" freezers is not recommended. If slight turbidity occurs upon prolonged storage, clarify the solution by centrifugation before use. Working dilution samples should be discarded if not used within 12 hours.
Product Profile
A minimum working dilution of 1:4,000 is determined by immunoblotting using a cytosolic fraction of rat brain. sGCβ1 is immunoprecipitated from 60 to 120 µg of a cytosolic fraction of rat brain using 2 to 3 µg of the antibody.

A minimum working dilution of 1:200 is determined by indirect immunoperoxidase staining of trypsin-digested, formalin-fixed, paraffin-embedded human heart sections.

Note: In order to obtain best results in different techniques and preparations we recommend determining optimal working dilution by titration test.
