mrs 2395: p2y12 purinoceptor antagonist
first available from sigma-rbi

prod. no. m 5942

p2 receptors are divided into two classes based on their molecular structure and signal transduction mechanisms: p2y receptors exist as g protein-coupled receptors while p2x receptors exist as ligand-gated ion channels [1]. these receptor subtypes are found in both the central and peripheral nervous system, the cardiovascular system, the endocrine system, lung, intestine, muscle and the immune system [2].

mrs 2395 is a recently described p2y12 purinoceptor antagonist that has been show to inhibit adp-induced aggregation in rat platelets, displaying a k_i value of 3.7 µm [2].

mrs 2395 is one of the first identified p2y12 purinoceptor antagonists, giving researchers a novel tool for studying the function of this receptor subtype as well as its role in various physiological functions.

sb-258585: highly selective 5-h-t6 serotonin receptor antagonist

prod. no. s 1194

serotonin (5-hydroxytryptamine, 5-ht) receptors have been classified by structural, functional and pharmacological criteria into seven distinct receptor classes referred to as 5-h-t1 - 5-h-t7. as compared with other 5-ht receptors, the function of the 5-h-t6 receptor is largely unknown.

sb-258585 was recently identified as a potent antagonist at 5-h-t6 receptors, displaying greater than 100-fold selectivity for 5-h-t6 receptors over 10 other 5-ht receptors investigated [1]. radioligand binding studies have shown that [125i]-sb-258585 binds with high affinity to both recombinant and native 5-h-t6 receptors from rat, pig and human brain and exhibits p_k_i values in the range 8.5-9.1 [2]. subsequent autoradiographic studies performed in rat brain using [125i]-sb-258585 indicated a distribution of 5-h-t6 receptor binding sites that suggests their possible involvement in locomotor control, cognition, memory and control of affect [3].

sb-258585 should prove, therefore, to be a useful tool for probing the function of 5-h-t6 receptors in the central nervous system.

anti-transportin 1: nuclear import receptor marker

prod. no. t 0825

clone d45, developed in mouse purified mouse immunoglobulin in phosphate-buffered saline

immunogen: recombinant human transportin [1]

isotype: igg1

species reactivity: human, mouse, rat, bovine, canine

transport of molecules to and from the nucleus is crucial for cell function. both the entry and exit processes play an important role in the regulation of diverse cellular processes including growth factor-mediated signaling, stress responses, cell cycle control and gene transcription/translation [2].

molecules requiring nuclear transport are diverse and comprise proteins as well as rna-protein complexes (rnps, ribonucleoproteins). proteins and rnas are imported and exported through nuclear pore complexes (npcs) that perforate the double bilayer of the nuclear envelope [3]. transportin 1 is a member of the importin β family of nuclear import receptors. transportin is responsible for importing heterogeneous nuclear ribonucleoprotein (hnrn) a1 back to the nucleus after it exports mrna.

transportin 1 is localized in the cytoplasm, nucleoplasm, and nuclear rim, similar to the localization of importin β. this suggests that transportin 1 may interact with npc during translocation.

immunoblot using a he la nuclear extract detected a band at 90 kda. in addition, the antibody may be used for immunoprecipitation and immunocytochemistry.
