Bone Morphogenetic Protein Receptor IA (BMPR-IA)/Fc Chimera
Human, Recombinant
Expressed in mouse NSO cells

Product Number B 2930

Product Description
Bone Morphogenetic Protein Receptor IA (BMPR-IA)/Fc Chimera is produced from the extracellular domain of human BMPR-IA. The protein is fused to the carboxy-terminal 6X histidine-tagged Fc region of human IgG1 by a polypeptide linker. Each subunit of human BMPR-IA, a homodimeric protein with a blocked amino-terminus, contains 372 amino acid residues (residues 24 -152 of BMPR-IA plus 243 amino acid residues from the Fc and peptide linkers). The calculated molecular mass of each subunit is approximately 41.5 kDa. Due to glycosylation, BMPR-IA migrates as a 55 kDa protein under reducing conditions in SDS-PAGE. Human and mouse BMPR-IA are highly conserved and share 98 % amino acid sequence identity.

Bone Morphogenetic Proteins (BMP) are members of the TGF-β superfamily of cytokines that affect bone and cartilage formation.2, 3, 4 Similar to other TGF-β family proteins, BMPs are highly conserved across animal species. Mature BMPs are 30 to 38 kDa proteins that assume a TGF-β-like cysteine knot configuration. Unlike TGF-β, BMPs do not form latent complexes with their propeptide counterparts. Most BMPs are homodimers, but bioactive natural heterodimers have been reported. Recently it was found that lovastatin (Mevinolin, Sigma Product M 2147), widely used for lowering cholesterol, also increases bone formation by turning on a gene (bmp-2) that promotes local bone formation.5 BMPs are involved in embryogenesis and morphogenesis of various tissues and organs. They create an environment conducive for bone marrow development by stimulating the production of specific bone matrix proteins and altering stromal cell and osteoclast proliferation.6, 7 In addition to stimulating ectopic bone and cartilage development, BMPs may be an important factor in the development of the viscera. BMPs regulate the growth, differentiation, chemotaxis, proliferation, and apoptosis of various cell types, including mesenchymal cells, epithelial cells, hematopoietic cells, and neuronal cells.2, 8 BMPs also appear to be responsible for normal dorsal/ventral patterning and can found in tissues that induce bone or cartilage growth such as demineralized bone and urinary epithelium.

Cellular responses to BMPs are mediated by the formation of hetero-oligomeric complexes of the type I and type II serine/threonine kinase receptors9 which play significant roles in BMP binding and signaling.

Bone Morphogenetic Protein Receptor IA (BMPR-IA), also known as activin receptor-like kinase (ALK)-3, is a type I serine/threonine kinase required for the signal transduction of the TGF-β family cytokines. BMP receptors include the type I receptors, BMPR-1A and BMPR-1B (50-55 kDa), and the type II receptor BMPR- II (70-80 kDa). These receptors are also closely related to the activin receptors ACV R1 and ACV R2. Type I receptors involved in BMP signaling can independently bind the various BMP family proteins in the absence of type II receptors. Soluble BMPR-IA binds BMP-4 with high-affinity in solution and is a potent BMP-4 antagonist in vitro. In adult tissues, BMPR-IA is widely expressed, but the highest expression levels are found in skeletal muscle. BMPR-IA is also widely expressed during embryogenesis.

Reagent
Recombinant Human Bone Morphogenetic Protein Receptor IA/Fc Chimera is supplied as approximately 100 µg of protein lyophilized from a 0.2 µm filtered solution in phosphate buffered saline (PBS) containing 5 mg of bovine serum albumin

Preparation Instructions
Reconstitute the contents of the vial using sterile phosphate-buffered saline (PBS) containing at least 0.1% human serum albumin or bovine serum albumin. Prepare a stock solution of no less than 100 µg/ml.
Storage/Stability
Store at −20 °C. Upon reconstitution, store at 2 °C to 8 °C for one month. For extended storage, freeze in working aliquots. Repeated freezing and thawing is not recommended. Do not store in a frost-free freezer.

Product Profile
Recombinant Human Bone Morphogenetic Protein Receptor IA/Fc Chimera is measured by its ability to inhibit the biological activity of recombinant human BMP-4-induced alkaline phosphatase production by C2C12 cells. The ED_{50} for this effect is generally 0.1 to 0.3 µg/ml in the presence of 200 ng/ml of recombinant human BMP-4.

The ED_{50} is defined as the effective concentration of growth factor that elicits a 50 % increase in cell growth in a cell based bioassay.

Purity: > 90 % as determined by SDS-PAGE, visualized by silver stain.

Endotoxin level is < 0.1 ng/µg protein as determined by the LAL (Limulus amebocyte lysate) method.
